# D-Wave Quantum Annealer I

- D-Wave is a quantum annealer specialized for searching low energy;
  - ▶ optimization - low energy
  - ▶ **probabilistic sampling** - samples from many low-energy states
- What is quantum annealing?

Figure: Quantum annealing in energy landscape

[[https://bundesquantenallianz.de/Quantencomputing/Quantenannealer\\_en.shtml](https://bundesquantenallianz.de/Quantencomputing/Quantenannealer_en.shtml)]

# D-Wave Quantum Annealer II

- Qubit of D-Wave : superconducting loop (spin) - one or more Josephson junctions
- Zephyr topology : 20 connectivity

Figure: Zephyr topology; A black dot represents a qubit

## D-Wave Quantum Annealer III

Example :  $2 \times 2$  2D Ising model

$$H_{\text{Ising}} = h \sum s_i + J \sum s_i s_j \quad (1)$$

$$H_{\text{QUBO}} = \sum x_i Q_{ij} x_j \quad (2)$$

under change of variable  $s_i = 2x_i - 1$ ,  $s_i \in [-1, 1]$ ,  $x_i \in [0, 1]$

QUBO(Quadratic Unconstrained Binary Optimization) matrix  
in upper triangular form

$$Q = \begin{pmatrix} 8 + 2h & -8 & -8 & 0 \\ 0 & 8 + 2h & 0 & -8 \\ 0 & 0 & 8 + 2h & -8 \\ 0 & 0 & 0 & 8 + 2h \end{pmatrix} \quad (3)$$

- 1 D-Wave
- 2 Motivation**
- 3 Methodology
- 4 Measurement
- 5 Future work - sampling
- 6 D-Wave application to experiment

# Motivation I

- Limitation of number of qubits and their connectivity.
  - ▶ maximized  $L = 64$
  - ▶ for 2D Ising model with OBC [theoretically]
  - ▶ whereas  $L = 11$  or  $12$  with PBC
  - ▶ 4800 qubits D-Wave cloud (Zephyr topology)

⇒ Our idea : using D-Wave to update sub-lattice,  
such as  $32 \times 32$  ( $l = 32$ ), iteratively  
for larger size  $L > 64$

## Goal

Propose highly improved algorithm for 2D Ising model  
using the **hybrid** MCMC algorithm with D-Wave annealer.

- 1 D-Wave
- 2 Motivation
- 3 Methodology**
- 4 Measurement
- 5 Future work - sampling
- 6 D-Wave application to experiment

# Brief steps

Brief steps are

- ① **Estimate thermodynamic  $\beta$  from  $\alpha$  of QUBO matrix**  
By comparing between enumeration and D-Wave sampling on sub-lattice  $l \times l$
- ② **D-Wave sampling + Metropolis-Hastings algorithm**  
Checkerboard method of  $l \times l$  sub-lattices
- ③ **Measurement**  
Comparing their autocorrelations with other algorithm

## $\beta$ estimation I

2D Ising model Hamiltonian without external magnetic field ( $h = 0$ )

$$H = -J \sum_i \sum_j \left( s_{ij} s_{i+1j} + s_{ij} s_{ij+1} \right) \quad T_c = \frac{2J}{\log(1 + \sqrt{2})} \sim 2.269185J \quad (4)$$

We used 'Advantage2\_system1' D-Wave cloud for this research.

- Zephyr topology
- $N_{\text{qubit}} = 4800$  (4578, working  $N_{\text{qubit}}$ )
- annealing time = 20  $\mu\text{s}$
- qubit temp =  $20 \pm 1$  mK
- programming thermalization time = 1000  $\mu\text{s}$

## $\beta$ estimation II

Firstly, we examine the maximized number,  $N_{\text{block}}$ , of  $l^2 \times l^2$  blocks in QUBO matrix (using PBC)

$l$	2	3	4	5	6	7	8	9	10	11
$N_{\text{block}}$	35	15	8	5	3	2	2	1	1	1

Chain break fraction is proportional to size of  $l$ , it is recommended to use appropriate  $l$ .

## $\beta$ estimation III

Estimation  $\beta$  from  $\alpha$  as in

$$H = x^T Q x \quad (x \in \{0, 1\}), \quad q \sim \exp\left(-\frac{\alpha H}{T_{\text{QPU}}}\right) \quad (5)$$

For smaller  $l (\leq 6)$ , Boltzmann distribution  $p_i$  are given exactly by enumeration method. And for larger  $l$ , MCMC algorithms are used to estimate the probability distribution.

$$p_i = \frac{1}{Z} e^{-\beta E_i} \quad (6)$$

where  $Z$  is normalization factor and  $i$  denotes spin states  $\{s_i\}$ .

- KL divergence with enumeration method

$$D_{\text{KL}}(p||q) = \sum_i p_i \log \frac{p_i}{q_i} \quad (7)$$

where  $p$  is from enumeration,  $q$  from D-Wave sampling

## $\beta$ estimation IV

- By minimizing KL divergence ( $l = 4$  case)

$\alpha : 0.005$		
$\beta_{\text{estimated}} : 0.040983$		
$T_{\text{QPU}} : 0.122002$		
Observable	D-Wave	Exact
$\langle E \rangle$	-1.3174	-1.3174
$\langle  M  \rangle$	3.4548	3.4423

Energy	D-Wave Freq	Exact Prob
-24	0.12 %	0.13 %
-20	0.26 %	0.22 %
-16	1.29 %	1.21 %
-12	4.14 %	4.20 %
-8	13.85%	13.79%
-4	23.20%	23.74%
-0	31.01%	30.48%
4	17.14%	17.11%
8	6.98 %	7.16 %
12	1.6 %	1.57 %
16	0.36 %	0.33 %

- $\beta$  Estimation from D-Wave is well done; But there is thermal fluctuations.

# Hybrid algorithm I

Checkerboard of  $l \times l$  sub lattice sampling  
(ex.  $L = 4, l = 2$  case; even  $\blacksquare$  / odd  $\square$ )

- $\beta$  estimation :  $(L/l)^2$   $l \times l$  sub-lattices (OBC)  
We observe local thermal deviation on the chip
- Initialize whole lattice ( $L \times L$ ) with D-Wave samples used for  $\beta$  estimation
- $n \times n$  sub-lattice update with fixed boundary condition

## Hybrid algorithm II

- Acceptance rate

$$A(\text{old} \rightarrow \text{new}) = \min \left\{ 1, \exp \left[ - (\beta_{\text{block},i} - \beta_{\text{avr}}) \Delta E \right] \right\} \quad (8)$$

where  $(\beta_{\text{block},i} - \beta_{\text{avr}})$  term corrects thermal deviation(local) and fluctuation(time) of the chip.

- $\beta$  update per 20 sweeps (fixed boundary condition) considering thermal fluctuation of the chip during calculation
- To stabilize  $\beta$  fluctuation from the same  $\alpha$ , we use sufficiently large `num_reads(=5000)` and choose averaged  $\beta$  after repeat 3 times  $\beta$  estimation.

- 1 D-Wave
- 2 Motivation
- 3 Methodology
- 4 Measurement**
- 5 Future work - sampling
- 6 D-Wave application to experiment

# Measurement I

- $\beta = 0.010565$  from  $\alpha = 0.001$   
 $T = 94.6$  (hot)

Spin Lattice Configuration (M=-14)

Energy Timeseries

|M| Timeseries

Autocorrelation Function

# Measurement II

- $\beta = 0.728445$  from  $\alpha = 0.1$   
 $T = 1.37$  (cold)  
(Early stopped)

Spin Lattice Configuration (M=-62)

Energy Timeseries

$|M|$  Timeseries

Autocorrelation Function

- 2 Motivation
- 3 Methodology
- 4 Measurement
- 5 Future work - sampling**
- 6 D-Wave application to experiment

# Future work I

## 2D Ising model

- Estimate the variance of  $T_{\text{QPU}}$  for local position on the chip over time.
- Reduce the fluctuation (dynamic embedding, Hamiltonian invariant transformation) to improve acceptance rate
- Larger size  $L = 64, 128, \dots$  with larger  $l = 32$

## Application to more complex theory

- $Z_2$  gauge theory   $H = \sum s_{ij} \times s_{ij+1} \times s_{i+1j+1} \times s_{i+1j}$ 
  - ▶ confinement
- SU(3) EFT in strong coupling limit
  - ▶ sign problem
  - ▶ finite temperature

- 1 D-Wave
- 2 Motivation
- 3 Methodology
- 4 Measurement
- 5 Future work - sampling
- 6 D-Wave application to experiment**

# D-Wave application to experiment I

- It can be used for DL model learning on experiment
- Through optimization of loss function
- But now it plays an assistant role; not a whole DL model training, but a part of it; because of its performance limitation.
- I'm staying tuned.

# Appendix I

Target distribution is

$$\pi(x) = \frac{1}{Z_{\text{target}}} \exp \left[ -\beta_{\text{target}} E(x) \right] \quad (9)$$

And the probability of QPU-proposed configuration  $y$  from  $x$ ,  $g(x \rightarrow y)$  is *independent* on the previous configuration  $x$

$$g(x \rightarrow y) = p_{\text{QPU}} = \frac{1}{Z_{\text{QPU}}} \exp \left[ -\beta_{\text{QPU}} E(x) \right] \quad (10)$$

Accept probability

$$p_{\text{accept}} = \min \left[ 1, \frac{\pi(y)g(y \rightarrow x)}{\pi(x)g(x \rightarrow y)} \right] \quad (11)$$

$$= \min \left\{ 1, \exp \left[ -(\beta_{\text{target}} - \beta_{\text{QPU}}) \Delta E \right] \right\} \quad (12)$$

## Appendix II

Detailed balance

$$\pi(x)P(x \rightarrow y) = \pi(y)P(y \rightarrow x) \quad (13)$$

where  $P(x \rightarrow y) = g(x \rightarrow y)A(x \rightarrow y)$
